**Tyre CPD**

**Uniform – Changing Area**

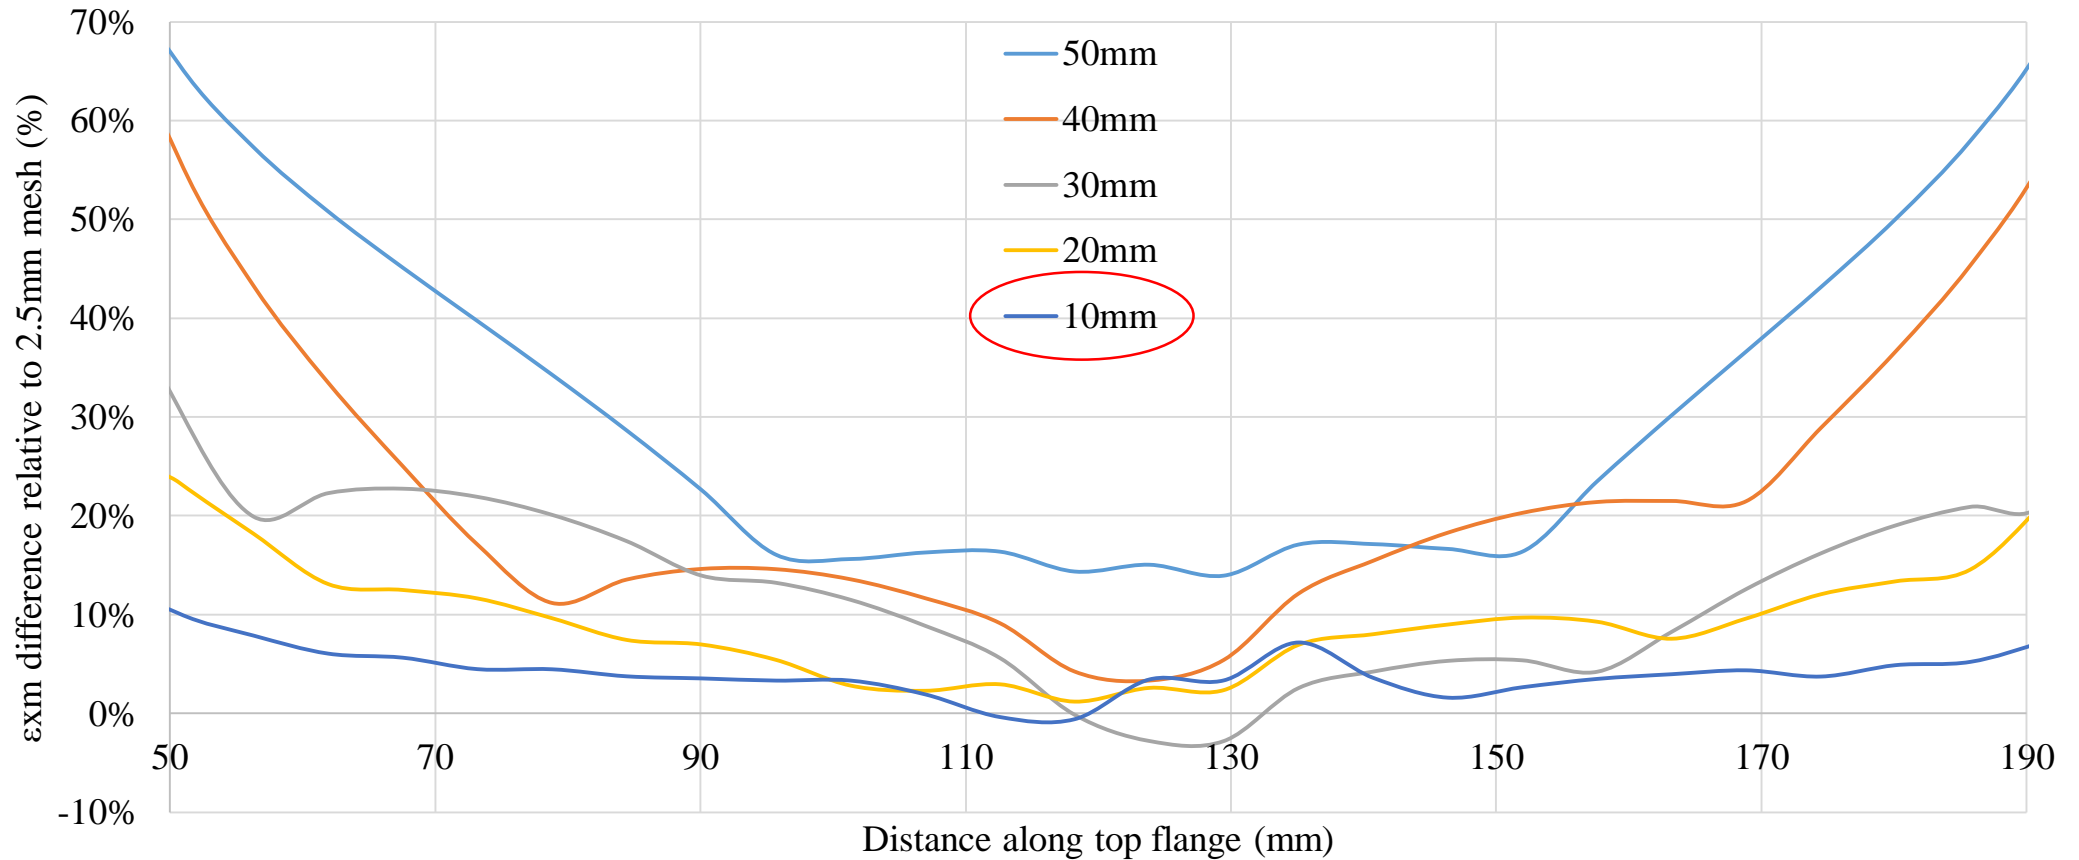

# Uniform-Square with Changing Area

### % Difference Relative to 2.5mm Mesh

- The tyre CPD is highly non-uniform, dependent on load, inflation pressure and tyre construction.
- A steel plate-pad does not produce a uniform CPD when applied to an FRP deck.
- The changing tyre CPD produced a non-linear load strain response, whereas the plate-pad produced a linear response.
- The measured CPD from a pressure sensor mat can be directly imported into an FE model of the deck.
- A uniform-square CPD with equal contact area to the real tyre at each load can reasonably replicate the local strains at midspan.

- CPD measurement of various tyre constructions at different loads and inflation pressures.
- Application of measured CPD to full 3D FE model of ASSET deck.
- Classification of fibre waviness and other defects to be included in FE model.
- Quasi-static and fatigue testing of web-flange-junction of pultruded GFRP decking systems.
- Application of acoustic emission and digital image correlation to assessment of local effects.

**Thank you**
